

Distribution of **all** interactions ($A^{(m),+}$, $A^{(m),-}$)

= Distribution of **Generalizable** interactions

+ Distribution of **Non-generalizable** interactions

Caption: Split-ratio ablation on CIFAR-10 with VGG11. $\mathcal{R}$ denotes the ratio of the number of samples used to train the target DNN to that used to train the baseline DNN. Across various $\mathcal{R}$, when $k = 5$, the generalizable interactions remain decay-shaped, while the non-generalizable interactions remain spindle-shaped, showing that our conclusion is stable across different data split ratios.
